c. Description of Serial Control Operations

- Each serial command consists of 16 bits of data which is loaded one bit a time at the rising edge of serial clock SCL
- Command loading operation starts from the falling edge of CS and is completed at the next rising edge
- The serial control block is operational after power on reset, but commands are established by the VSYNC signal. If command is transferred multiple times for the same register, the last command before the VSYNC signal is valid. Please refer to Fig. 5.
- If less than 16 bits of SCL are input while CS is low, the transferred data is ignored.
- If 16 bits or more of SCL are input while CS is low, the first 16 bits of transferred data before the rising edge of CS pulse are valid data.
- Serial block operates with the SCL clock and serial data can be accepted in the power save mode

panel

output

Note 4. Definition of response time: The signals of photo detector are measured when the input signals are changed from "black" to "white"(falling time) and from "white" to "black"(rising time), respectively.

The response time is defined as the time interval between the 10% and 90% of amplitudes. Refer to

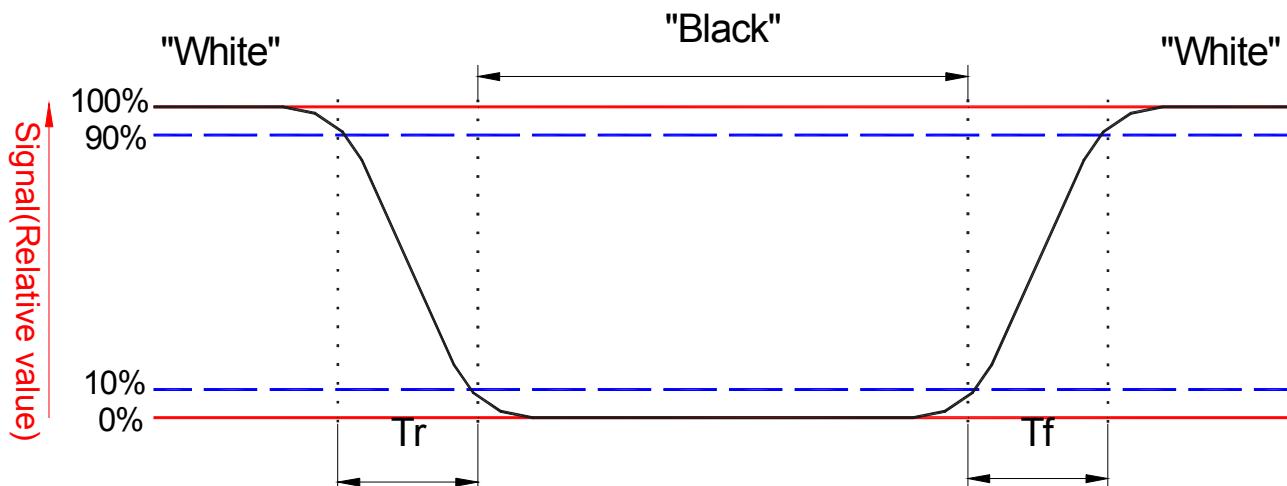

figure as below.

Note 5. Definition of contrast ratio:

Contrast ratio is calculated with the following formula.

$$\text{Contrast ratio (CR)} = \frac{\text{Photo detector output when LCD is at "White" state}}{\text{Photo detector output when LCD is at "Black" state}}$$

Note 6. White $V_i = V_{i50} \pm 1.5V$

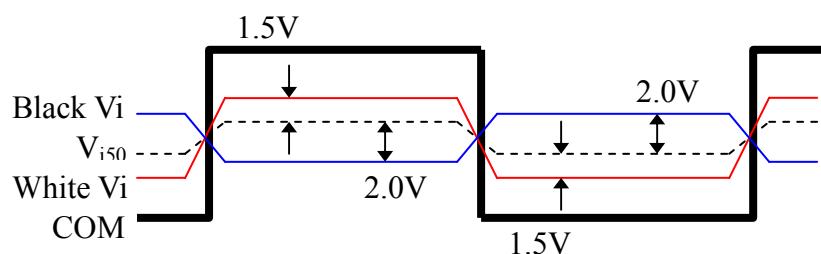

Black $V_i = V_{i50} \mp 2.0V$

" \pm " Means that the analog input signal swings in phase with COM signal.

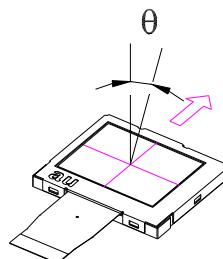

" \mp " Means that the analog input signal swings out of phase with COM signal.

V_{i50} : The analog input voltage when transmission is 50%

The 100% transmission is defined as the transmission of LCD panel when all the input terminals of module are electrically opened.

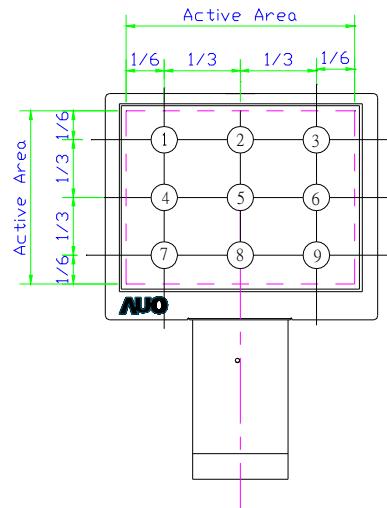

Note 7. Definition of viewing angle:

Note 8. Measured at the center area of the panel when all the input terminals of LCD panel are electrically opened.

Note 9. Definition of luminance uniformity

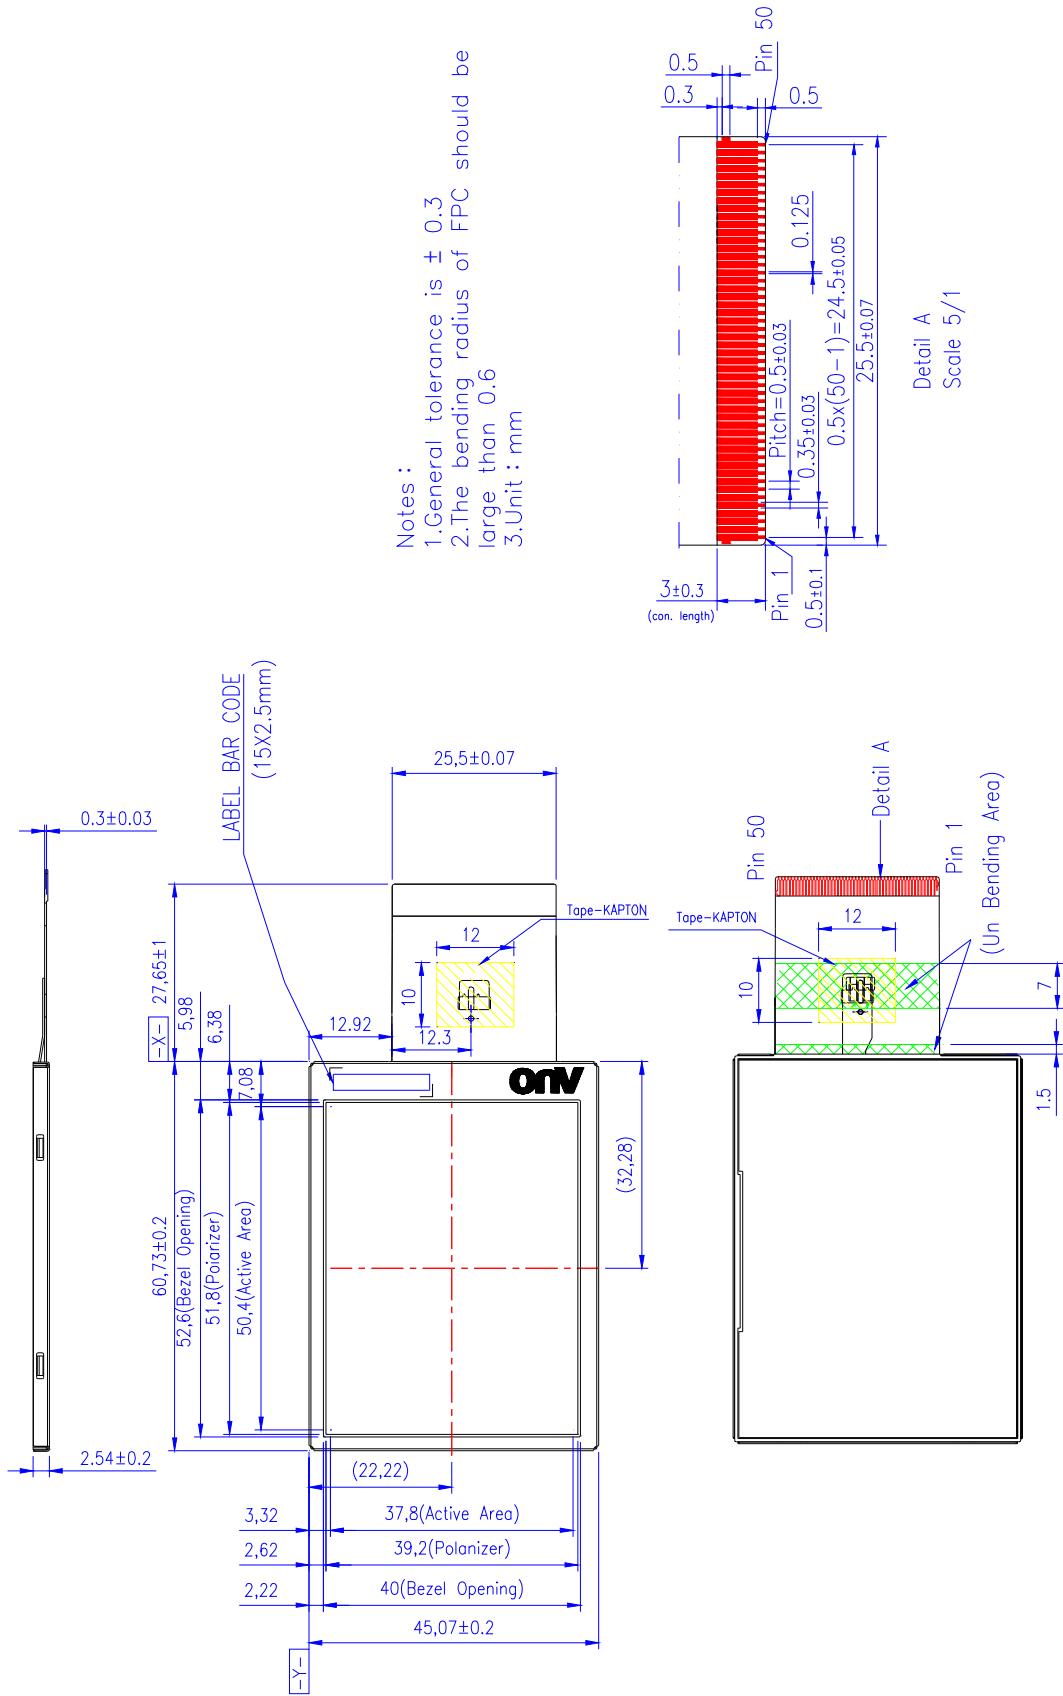

$$\text{Luminance Uniformity} = \frac{\text{Min. Brightness of nine point}}{\text{Max. Brightness of nine point}}$$

G. Application Notes

This LTPS TFT LCD module is designed for digital still camera application. A COG type LCD driver IC is integrated within this module, makes it much easier to design and cost-effective. The main features of integrated driver are:

- Accepting digital R, G, B 6-bit signal, fewer adjustment, fewer design effort, and lower power consumption compared to other analog LTPS solution.
- Integrated timing controller for RGB666 input timing formats. For RGB666 input timing, the input signal is always the same for different panel resolution.
- Integrated LED power converter controller, DC-DC charge pump, and Vcom driver. A design requires less peripheral components and reduces the total system cost.

1. Input Data Timing

In RGB666 input format, the mapping of incoming data to display dots is take cared by built in scaling function of driver IC.

There are only one input RGB data mode: 320xRGBx240. Input data is processed and mapped to display dots by integrated driver IC according to panel resolution and scan direction settings. RGB666 input format saves the effort of data scaling for users and keeps a consistent interface for different display resolutions, in the cost of higher input data rate and less image processing elasticity.

For vertical input timing, RGB666 accept odd / even field switching or single field only input. For detail timing spec., please refer to Fig 2.

2. Typical Application Circuit

a. Internal LED booster circuit

The integrated driver IC provides build-in LED booster controller, DC-DC charge pump, and Vcom driver. See Fig. 6 for the application circuit.

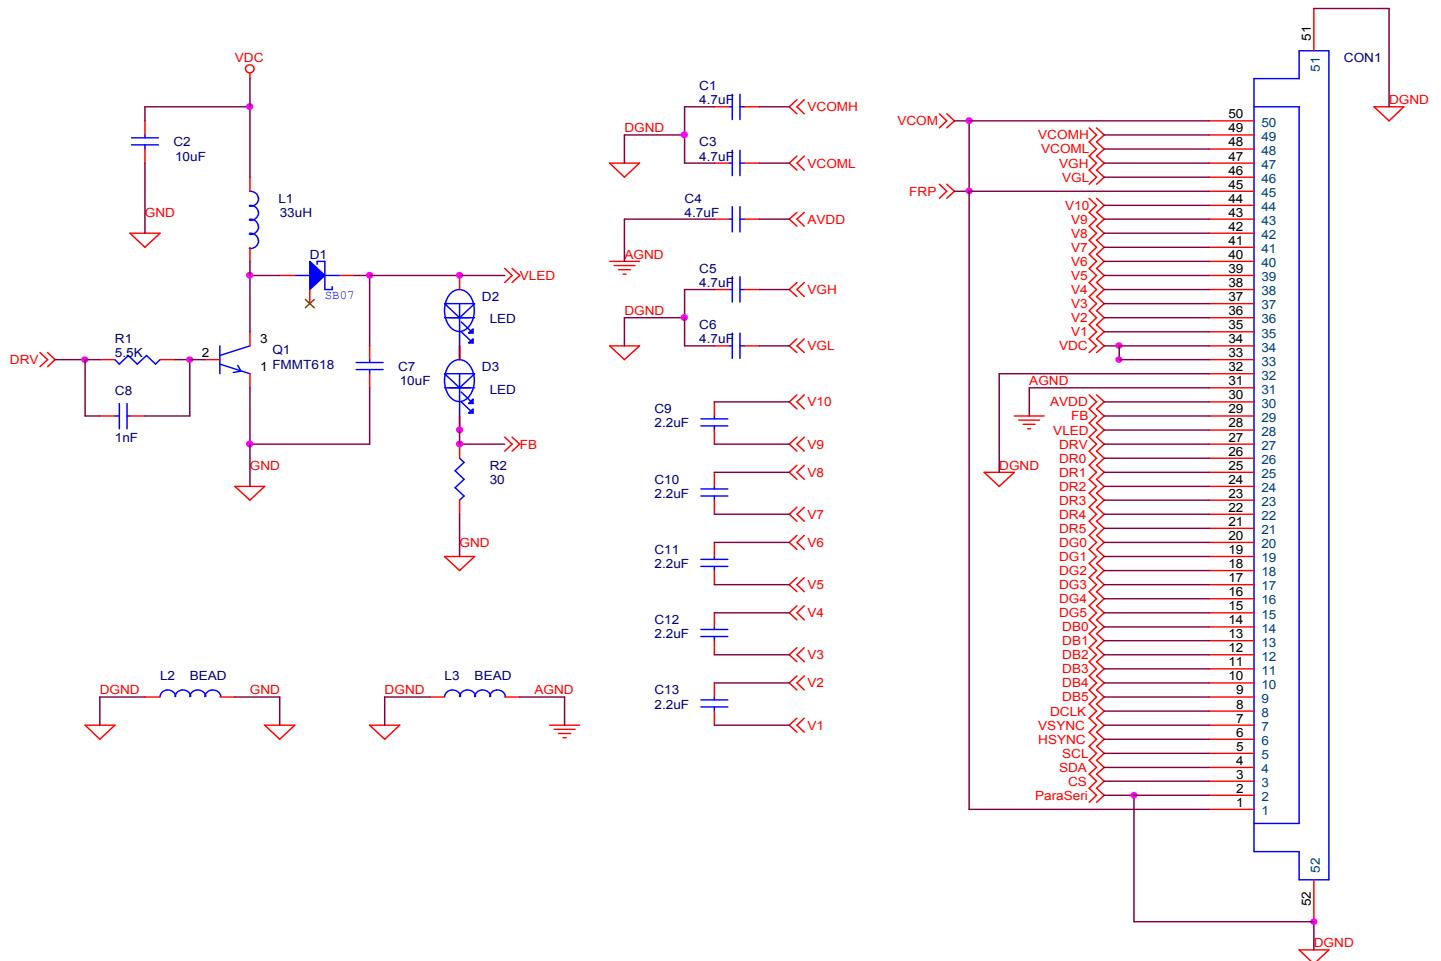

Fig. 6 Typical Application Circuit

<Note> : The charge pump frequency is about 7~8KHz, which can be heard by human. To prevent this signal from being amplified by microphone or other audio recoder, C9~C13 are suggested to be kept as far away as possible from these devices.

b. External LED driver circuit

See Fig. 7 for the application circuit.

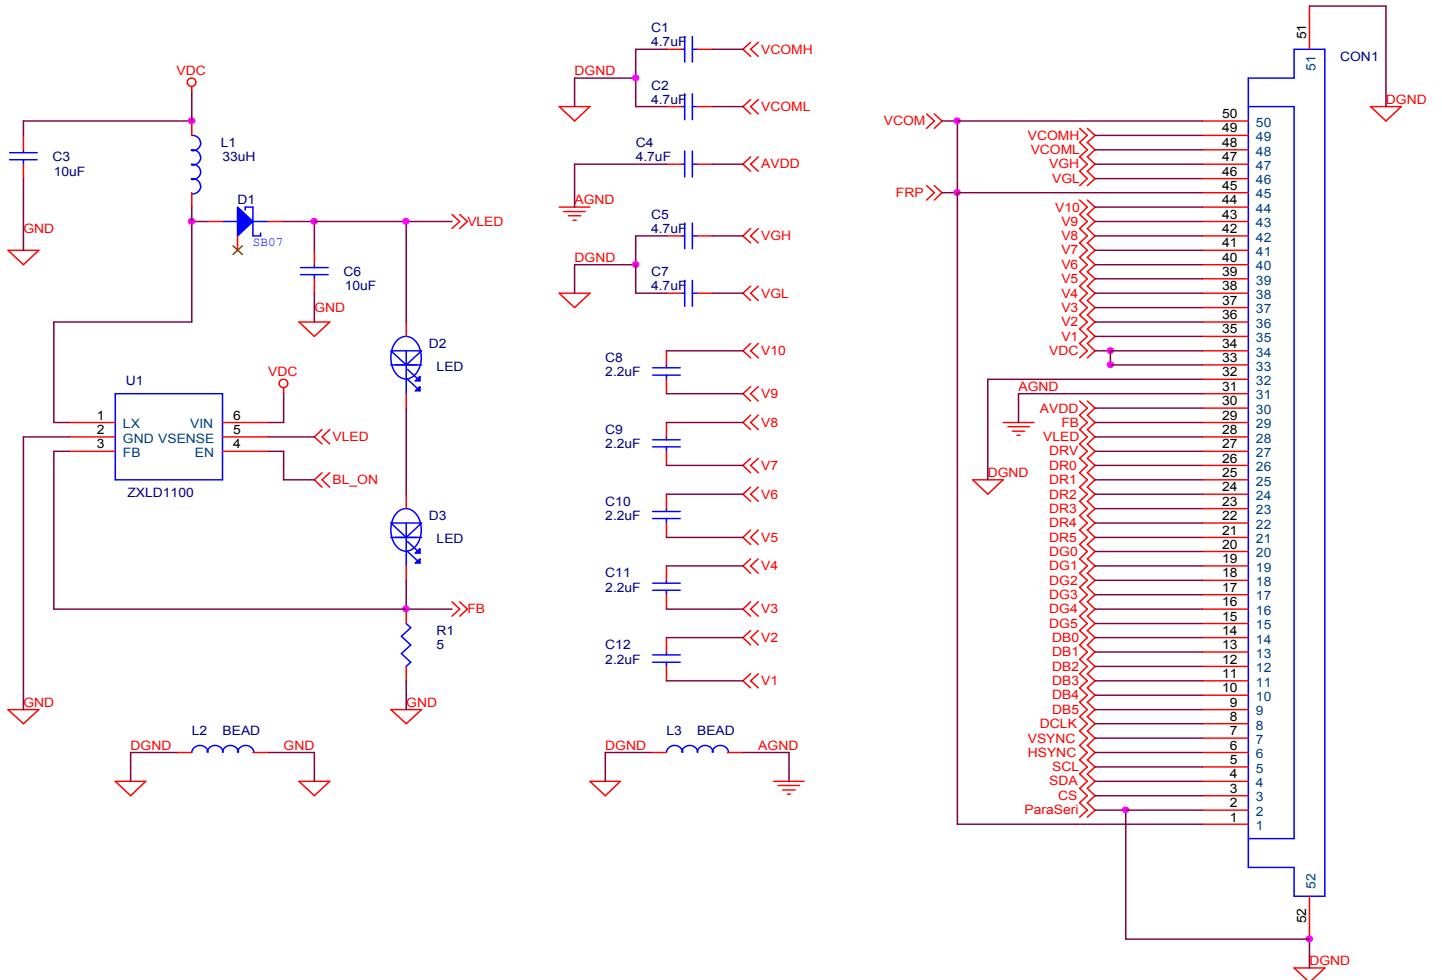

Fig. 7 External LED Driver Application Circuit

Single power VDC (Typical 3.3V) is required to provide driver IC power and generate all necessary voltages for LCD related circuits.

According to Fig. 7, the LED driver(ZXLD1100) and R1(5 ohm) with 0.1V feedback (FB) can provide a constant 20mA current for LED backlight unit. To control the back light on/off timing, user should create a control signal BL_ON (please refer to the ZXLD1100 date sheet). The LCD driver output DRV signal can also be used to drive BL_ON.

<Note> : The charge pump frequency is about 7~8KHz, which can be heard by human. To prevent this signal from being amplified by microphone or other audio recorder, C8~C12 are suggested to be kept as far away as possible from these devices.

3. Power ON/OFF Sequence

The register setting of standby mode disabling / enabling is used to control the build-in power on / off sequence.

a. Power On (Global Reset and Standby Disabling)

After V_{DC} power on reset, VSYNC/HSYNC/DCLK/DATA can be input, and serial control interface is also operational. To ensure that panel can be lighted on successfully, the first step is setting global reset (register #5 "16(hex)") as the timing in Fig. 9. Then the LCD driver is in default standby mode after V_{DC} power-on, and setting register #5 bit #0 to high (STB=1) to disable the standby mode is required for normal operation. When the standby mode is disabled, a build-in power on sequence is started. The driver IC analog power AVDD is turned on first, and then the LCD positive and negative power supplies VGH/VGL are pumped, and followed by the LED power VLED. Since we recommend using external LED driver, the BL_ON signal (see Fig.8) should be provided at this time. Please refer to Fig.8 and Fig. 9 for the detail timing of power on/off sequence, especially the global reset timing in Fig. 9.

b. Power Off (Standby Enabling)

When the register #5 bit #0 is set to low (STB=0) to enable standby mode, a build-in power off sequence is started. Please refer to Fig.8 for the detail timing. No serial command programming is allowed right after standby mode is enabled, for a time period of minimum 5 fields.

c. Clock Stop Reset

The DCLK signal is required for normal operation. When the DCLK is stopped for more than 5.6 μ sec (or DCLK frequency < 140KHz) during normal operation, the driver IC will be reset and operated in standby mode. This DCLK stop reset does not affect the serial interface settings.
